Smart Grids and Microgrids

Smart Grids and Microgrids are important concepts in the field of power system analysis and design. In this explanation, we will cover key terms and vocabulary related to these concepts.

Smart Grids:

A Smart Grid is an electrical power system that uses advanced technology to optimize the production, transmission, and consumption of electricity. It enables two-way communication between the utility and its customers, allowing for the sharing of information and the remote control of devices.

Microgrids: A Microgrid is a localized group of electricity sources and loads that normally operates connected to the traditional grid, but can also operate autonomously.

Advanced Metering Infrastructure (AMI): AMI is a system of smart meters, communication networks, and data management systems that enables two-way communication between the utility and its customers. It provides detailed information about electricity usage, enabling customers to better manage their energy consumption and utilities to more accurately bill their customers.

Demand Response (DR): DR is a program that allows utilities to reduce electricity demand during peak periods by offering incentives to customers to reduce their electricity usage.

Distributed Energy Resources (DERs): DERs are small-scale electricity generation and storage technologies, such as solar panels and batteries, that are connected to the distribution grid.

Advanced Distribution Management Systems (ADMS): ADMS is a software system that enables utilities to manage the distribution grid in real-time, including the control of DERs.

Phasor Measurement Units (PMUs): PMUs are devices that measure the voltage and current at a specific point in the power grid and provide precise time-stamped data. This data is used to monitor the grid's stability and to detect and locate faults.

Synchrophasors: Synchrophasors are time-synchronized measurements of voltage and current provided by PMUs. They are used to monitor the grid's stability and to detect and locate faults.

Fault Detection and Location (FDL): FDL is the process of identifying and locating faults in the power grid using synchrophasor data.

State Estimation (SE): SE is the process of estimating the state of the power grid using synchrophasor data. It is used to monitor the grid's stability and to detect and locate faults.

Wide Area Monitoring, Protection, and Control (WAMPAC): WAMPAC is a system that uses synchrophasor data to monitor and control the power grid in real-time.

Microgrid Control Systems: Microgrid control systems are software systems that enable the control and management of microgrids. They include functions such as voltage and frequency control, load balancing, and islanding detection.

Islanding: Islanding is the condition where a microgrid continues to operate while disconnected from the traditional grid.

Peak Shaving: Peak shaving is the process of reducing electricity demand during peak periods by using stored energy from batteries or other storage devices.

Volt-VAR Control: Volt-VAR control is the process of controlling the voltage and reactive power in a power system to maintain the desired voltage levels and power factor.

Microgrid Interconnection Standards: Microgrid interconnection standards are guidelines that specify the technical requirements for connecting a microgrid to the traditional grid.

Microgrid Ownership Models: Microgrid ownership models refer to the different ways in which a microgrid can be owned and operated, such as utility-owned, customer-owned, or third-party-owned.

Microgrid Business Models: Microgrid business models refer to the different ways in which a microgrid can generate revenue, such as through the sale of electricity, demand response, or ancillary services.
